## Abstract

An ethnobotanical survey was carried out in the region called Pallars—consisting of two districts, Pallars Sobirà and Pallars Jussà—, situated in the Central Pyrenees, in North West Catalonia (Iberian Peninsula), with an approximate area of 2530 km<sup>2</sup> and a population of 19 000. Through interviews with 264 people, we obtained data on 437 plant species used for health care. We detected 867 unreported or uncommon uses corresponding to 272 plant species, 52 of which had never or very rarely been cited as medicinal. This is the second paper of a series intended to present the most important findings concerning the ethnopharmacology of the area studied; it includes unreported or very uncommon uses of known medicinal plant species. A previous paper reported the general results and the new or very scarcely reported medicinal vascular plants, and a further one will deal with medicinal non vascular plants.

## 1. Introduction

Ethnobotany can be very broadly defined as the study of the interactions between plants and people in their local environment (Martin, 2001). We can distinguish two different goals or approaches to this study: the contribution to the knowledge of a part of human cultural heritage and the search for new drugs or useful plant-derived products. Ethnopharmacology more usually related to this second goal, but is also concerned with the first one. As a multidisciplinary field, it must take into account the perspective of finding products, which can enhance human health, not forgetting the social structure, richness and problems of the communities from which the information is taken. As Etkin (2001) recently claimed, a higher degree of interdisciplinary activity is needed in ethnopharmacological studies.

Having in mind the precedent statements, we have been conducting for the last 15 years ethnobotanical researches in different regions of Catalonia (see Bonet et al., 1999, and references therein) with the 2-fold purpose of contributing to the knowledge and the preservation of a part of the national cultural heritage, and finding out new or rare uses of medicinal plants, which could lead to the use of new plant-based medicines. This kind of research, much rarer in Western Europe than in less industrialized areas, has largely increased in the last decade in the countries of the Iberian Peninsula. The list of Iberian contributions to ethnobotany—basically pharmaceutical ethnobotany—given in Raja et al. (1997) and updated in Bonet et al. (1999), Agelet and Vallès (2001) has been supplemented by the recent works of Torres (1999), Blanco et al. (1999, 2000), Álvarez (2000), Blanco and Cuadrado (2000), Villar and Ferrández (2000), Bonet (2001), Bonet et al. (2001), Rodrigues (2001).

Our work in the region presently considered was also conducted with both above-stated objectives. This paper follows a previous one based on the same territory

E-mail address: [avalles@farmacia.far.ub.es](mailto:avalles@farmacia.far.ub.es) (J. Vallès).

(Agelet and Vallès, 2001) and presents the second part of the results dealing with the applied research on popular phytotherapy that is relevant for the search for new drugs, on the basis of the conviction that plants from the Mediterranean region have a real medicinal potential. In the first paper we treated the plants which were not previously mentioned as medicinal in the literature and the present one deals with the new or very rare uses of already known medicinal plants. The territory studied is called Pallars, constituted by two mountain districts ('comarca', in plural 'comarques', in Catalan) situated in the Pyrenees: el Pallars Jussà (or el Baix Pallars) and el Pallars Sobirà (or l'Alt Pallars). The geographical and socioeconomic description of the area considered is given in Agelet and Vallès (2001).

## 2. Methodology

Information was obtained, as detailed in Agelet and Vallès (2001), by the method of the ethnobotanical interview with people without scientific culture, born or having lived most of their lives in the region studied, and usually quite elderly. During our meetings with people, we tried to assess every question linked to the uses of plants by people with health purposes, in persons and animals. The field and laboratory work lasted more than 5 years, during which we performed 155 interviews (395 h of interview recorded) concerning 264 from 30 to 101-year old people (mean age, 70 years; 48% women, 52% men). Voucher herbarium specimens of every taxon cited were prepared and deposited in the Herbarium of the Laboratory of Botany, Faculty of Pharmacy, University of Barcelona (BCF). Complete records of the interviews are also kept in this Laboratory. Details on informants and the transcription of the interviews are given in the Doctoral Thesis of one of the authors (Agelet, 1999). For plant nomenclature, we follow Bolòs et al. (1993).

To establish the originality of our research, we compared our results with an extensive corpus of the most relevant Iberian and European ethnobotanical studies and a wide selection of other papers and treatises covering the uses of medicinal plants all over the world. These studies are the same as those used and cited by Raja et al. (1997), Bonet et al. (1999), Agelet and Vallès (2001), which, with the literature used to compare the results, reaches 77 papers.

## 3. Results and discussion

The Pallars ethnophytology (Agelet, 1999; Agelet and Vallès, 2001) consists of 529 species, 437 of which (82.6%) are used in the field of health, 60 (11.34%) have other uses (among which food is the most

important) and 32 (6.04%) have only popular names, but no use. The 437 health plants can be grouped in the following way, taking into account that one plant may belong at the same time to more than one group: 410 (93.82%) therapeutic, 94 (21.51%) prophylactic, 40 (9.15%) with magicoreligious use, 12 (2.74%) diagnostic elements, 55 (12.58%) with other uses linked with health; 146 (33.4%) plants are considered noxious or toxic.

The complete catalogue of the useful plants of the areas studied is given in Agelet (1999). We are presenting in this paper the unreported uses of plants already known as medicinal, as well as some comments on prophylactic and toxic properties of plants. The general results of the work concerning pharmaceutical ethnobotany as well as the information about plants unreported to date as medicinal are given in Agelet and Vallès (2001), and a further article will deal with the non-vascular medicinal plants used in the territories studied. Following a reliability criterion established in studies dealing with quantitative ethnobotany, such as Le Grand and Wondergem (1987) and Johns et al. (1990), we are presenting in Table 1 the 87 vascular medicinal plant species for which we found at least one use not reported in the literature and cited by three or more independent informants; they are grouped by families in alphabetical order.

### 3.1. Plants with uses cited by only one or two informants

The normal length of an article does not allow us to include in Table 1 the remaining 178 species with new or uncommon uses that have been only cited by one or two informants; a few of them will be shortly commented in this and the next subheadings, and Agelet (1999) can be consulted to find complete information on these plants and their uses. Irrespective of the usefulness of reliability criteria to validate folk uses of plants, we believe that plants cited by a very small number (even one) of informants must be taken into account, because, particularly in our European countries, they can be the last remainders of a wider knowledge of last generations, for which popular uses of plants were much more common. In addition, it is worth mentioning that some of the new or very scarcely reported uses cited by one or two informants are considered of particularly high efficacy by the informants. This means that knowledge of plants with these uses by people is not superficial and that they may also be reliable. We list here some examples: *Agave americana* L. (antialgic), *Anagallis arvensis* L. (salutiferous), *Arctium minus* Bernh (antiasthmatic, anticholagogue, antiherpetic), *Artemisia chamaemelifolia* Vill. (bechic), *Arundo donax* L. (antiulcerous), *Helichrysum stoechas* (L.) Moench. (antiprostatitic, ocular antiseptic), *Hieracium pilosella* L. (antigangrenous), *Lactuca sativa* L. (antidepressive), *Leuzea conifera* (L.) DC. in Lam. et DC. (for warts, hypotensive, oxytocic, for

bscesses), *Pinguicula vulgaris* L. (anti-inflammatory, vulnerary), *Rumex longifolius* DC. in Lam. et DC. (antidiarrhoeal, vulnerary), *Thymelaea tinctoria* (Pourr.) Endl. (antialgic, anti-inflammatory, antitoxic), and *Trigonella coerulea* (L.) Ser. in DC. (anticatarrhal, anticephalalgic).

### *3.2. New medicinal uses*

The number of new medicinal plant uses in Pallars is 745, and concerns 265 taxa. It raises to 867, concerning 317 taxa, if we count not only those of known medicinal plants—object of the present study—but those of new or very rarely reported medicinal plants ([Agelet and Vallès, 2001](#)) as well. This figures are very high in absolute value and in comparison with what is reported in work carried out in other Mediterranean regions (see references cited in table 2 of [Agelet and Vallès, 2001](#)). Some of the new or very scarcely reported uses can be found in the literature for taxa very closely related to those we are dealing with. This is the case, for instance, of *Inula helenioides* DC. in Lam. et DC., the antialgic activity of which is largely known in other species of the genus. Some of the new uses may be only slightly different from some others already reported for one plant. As an example, *Centaurea calcitrapa* L., considered to be hematocathartic (blood depurative) by our informants is reported as depurative—a concept that can include blood or not—by [Muntané \(1991, 1994\)](#). We must be also aware of some nomenclatural or terminological problems, i.e. the possible use of different medical terms to synthesize in one or a few words the concept expressed by the informants, which is often a difficult question. An illustration of this situation can be the troubles of the menstruation and the menstrual cycle. We interpreted as antiamenorrhoeal one of the uses claimed by our informants for *Ceterach officinarum*; for the same species, [Verde et al. \(1998\)](#) reported a use which fits the concept of antidysmenorrhoeal. The terms are very related and the use or one or another can depend on every author. Paying attention to [Etkin \(2001\)](#) assessment that a bigger interdisciplinary collaboration is required in ethnopharmacological studies can contribute to the solution of this problem. The application of the precedent statements in the analysis of the ethnopharmacological catalogue can slightly diminish the number of strictly new uses. In addition, some of the claimed plant properties (general salutiferous, intestinal antiseptic or vulnerary, for example) can be considered as not very strong, because they are known in many plants and usually related to not very serious illnesses. Irrespective of all the mentioned problems, and even if we do not pay attention to a certain amount of plants, the number of new or very rare medicinal plant uses still remains high. This is an argument that proves without any doubt that European plants can be

promising as a source of medicinal products and as a basis for further (chemical and/or pharmacological) investigations on this subject. In consequence, we can conclude that it is worth, even in the applied field of ethnopharmacology, conducting researches on European ethnobotany.

In fact, ethnobotanical researches continue to detect new or very rare plant uses, even in very well-known medicinal plants. This is the case, for instance, of *Sambucus nigra* L. Two of the uses reported in Pallars (to diminish blood thickness and antipneumonic) are new for this species, despite being one of the most widely known, appreciated and utilised plants in Catalonia (Muntané, 1991, 1994; Agelet, 1999; Bonet, 2001).

Most blood depurative plants have a large activity spectrum. They are often claimed to be useful against infections and infestations (antidermatosic, antiseptic, antipneumonic). This fact is particularly remarkable in seven species (*Abies alba* Mill., *Centaurea erythraea* Rafn, *Equisetum arvense* L., *Ramonda myconi* (L.) Reichenb., *Rosa canina* L., *Thymus serpyllum* L. and *Tilia platyphyllos* Scop.), which accumulate up to 26 uses concerning very different ailments. Anticholagogue plants form another group with many different activities: they are used for 15 different medicinal purposes.

### 3.3. Drug preparation methods

Most of the plants are used internally (68% over 32% externally). Tisanes (49.9%) and lotions (12.5%) are the two predominant preparation forms. Tisanes are seen by the informants as the most genuine products of folk phytotherapy. The predominance of these forms—particularly tisanes, obtained by infusion or decoction—agrees with the general results in our study in Pallars (Agelet and Vallès, 2001), and can also be found in neighboring regions (Mulet, 1990, 1991; Muntané, 1991, 1994; Bonet et al., 1992, 1999; Raja et al., 1997). It should be emphasized that in 20.6% of the remedies reported there is no pharmaceutical form, i.e. a part of the plant is directly used. Aerial part (29.7%) and leaves (14.5%) are the predominant plant portions used, which is also in agreement with the data in the above cited papers carried out in other Mediterranean areas. As an original use, involving a particular plant part, we can mention that of the galls formed by the insect *Diplolepis rosae* L. in *R. canina* L., which are claimed to have ocular and renal anti-inflammatory, antiodontalgic and renal antiseptic properties. Some elaborate products, such as olive or juniper oils, bread or vinegar are also used.

### 3.4. Drug activities

The main therapeutic groups of the new plant uses are coincidental with those of the complete Pallars pharma-

ceutical ethnoflora, and also agree with those reported for other Mediterranean territories: hypotensive, intestinal antiseptic, laxative, general salutiferous and anticatarrhal are the main activities. Stronger medicinal powers, such as against hypercholesterolemia (reported, among other species, for *Achillea millefolium* L., *Betula pendula* Roth., *E. arvense* L., *E. telmateia* Ehrh., *Fraxinus angustifolia* Vahl, *Parietaria officinalis* L., *Raphanus raphanistrum* L. subsp. *sativus* (L.) Domin., *R. canina* L. and *Rubus ulmifolius* Schott) or antigangrenous (*Hedera helix* L. and *H. pilosella* L.) have also been claimed for some species, but in a much lower proportion as compared with activities against mild and chronic diseases. Another strong plant use, antiophidian (against *Vipera* sp. bites), has been reported by our informants for *F. angustifolia* Vahl. This species is not included among the around 900 collected by Houghton and Osibogun (1993) in their review of flowering plants used against snakebite, although there is an Asian species of the same genus, *F. pubinervis* Blume.

### 3.5. Plants with possible immunostimulant applications

Plants that reinforce the immune system are of special interest in phytotherapy (Reuter, 1991). Thirteen species of Pallars medicinal ethnolflora have been reported to have immunostimulant or immunomodulating properties by several authors (Arnold-Apostolidis, 1991; Arteche et al., 1993; Bézanger-Beauquesne et al., 1990; Font, 1961; Peris et al., 1995; Reuter, 1991; Ribon, 1993; Rombi, 1991): *A. millefolium* L., *Althaea officinalis* L., *Bryonia cretica* L., *Calendula officinalis* L., *Cinnamomum zeylanicum* Nees, *Gentiana lutea* L., *Marrubium vulgare* L., *Matricaria recutita* L., *Pinus sylvestris* L., *Plantago lanceolata* L., *R. canina* L., *Rosmarinus officinalis* L., and *Viscum album* L. *Alchemilla alpina* L. could be added to this list, since a close species (*A. vulgaris* L.) has also immunomodulative activity (Reuter, 1991). All these taxa have been claimed, directly or indirectly, by our informants to be able to increase immunologic responses of the organism or to favor hematopoietic or trombocytopoietic processes. Antiseptic or salutiferous uses often attributed to these plants may be considered under this point of view, and the species concerned constitute a good group for chemical and/or pharmacological studies in view of their use in case of illnesses involving an immune system depression.

### 3.6. Prophylactic uses

The general results of our study (Agelet, 1999) and the data reported by other authors (Muntané, 1991; Parada, 1997) lead to the conclusion that preventive plant uses are not very common in folk phytotherapy. In Pallars, we found references to such properties in just 94 of the 437 species cited (21.5%), and no one taxon was used

with only prophylactic purposes. Antiseptic, general salutiferous and antiparasitic are the main uses in this field. In human medicine, some antihypertensive species are used for the prevention of apoplexy, as they are also in other territories (Villar et al., 1992). Most of prophylactic species are used in veterinary medicine. One species, *Ruta chalepensis* L., is used in phytopathology, in the preventive treatment of *Capsicum annuum* L. against mildew caused by *Phytophthora capsici* Leonian.

### 3.7. Toxic or noxious plants

Some of the new medicinal plant properties correspond to toxicity or other types of noxious activities. As we stated earlier (Agelet and Vallès, 2001) several plants that are well known as toxic by our informants are also used, with the necessary precautions, as medicinal agents. Conversely, some medicinal plants can become toxic if they are abusively or uncorrectly used. This is the case, in Pallars, of *Rumex pulcher* L., claimed to be antipyretic, diuretic and antihypertensive, the abuse of which can cause drastic hypotension. Most of the observed noxious activities correspond to weakening effects linked to the consumption of some plants during a long period of time. The debility caused can be general or particularly focused in the sense of vision. *Agrimonia eupatoria* L. (with, among other uses, antiapoplectic and antidermatosic), *Amelanchier ovalis* Medic. (antihaemastenic, antipyretic), *Urtica dioica* L. (antialgic, antiapoplectic, antipneumonic), and *Valeriana officinalis* L. (sedative, hematocathartic, hemostatic) share these weakening and/or amaurotic activities. In order to avoid these undesirable side effects, it is often advised not to take one or another plant during more than 7 or 9 days. Irrespective of the fact that some numbers, such as seven or nine, have some magic significance in folk medicine, the idea of taking a remedy during some days and then refraining from taking it during a similar period of time tends to counterbalance the possible toxic or adverse effects of this medicine. The same facts are observed in other Iberian territories (Peris and Stübing, 1993; Gavilanes, 1995; Bonet et al., 1999). Lethal uses reported by our informants refer to observations done on domestic animal (rabbits, pigs, sheeps or cows) feeding. Ten species are in this situation; some of them are always lethal (*Ballota nigra* L., *Brassica oleracea* L. subsp. *oleracea*, *M. vulgare* L., *Rubia peregrina* L.), whereas some others (*Genista balansae* (Boiss.) Rouy, *Medicago lupulina* L., *Quercus humilis* Mill., *Trifolium pratense* L., *T. repens* L., *Vicia ervilia* (L.) Willd.) are only occasionally lethal, in case of abuse or of ingestion in special circumstances, such as when the plant is humid and subsequently warmed by the sun.

Some plants known as toxic in internal administration can have medicinal external uses. A lotion prepared with the roots of *Sambucus ebulus* L. is considered to be

antieccchymotic in topical use, whereas most parts of the plant (including roots) are toxic (Boada and Romanillos, 1999). Mulet (1997) also reports some medicinal activity of this noxious plant. Even more, there are plant parts specifically known as toxic, which are used in Pallars folk medicine. This is, for instance, the case of *H. helix* fruits, reported to be haemolytic, emetic, purgative and even lethal (Boada and Romanillos, 1999), but taken in internal use in the region studied as a buccopharyngeal antiseptic and as an oxytocic.

### Acknowledgements

We are very grateful to all those 'pallaresos' who were willing to share with us the treasure of folk knowledge of plants, with a particular remembrance of our informants who have died. The editing task done by P.J. Houghton is thanked. This study was partially supported by grants from the Centre de Promoció de la Cultura Popular i Tradicional Catalana de la Generalitat de Catalunya.
